# Branches

Having a good branching strategy allows team members to work on different parts of the project independently. For starters we are going to have two big branches: main, and dev. In these two branches we will keep the production product and development product respectively. When creating a new branch to add a feature to the product the branch will be made from the dev branch. The rules we apply to this project are the following:

- It is not allowed to push directly on the main or dev branch
- Putting code on the main branch will be done with the use of a merge request.
- Before a merge request is accepted it needs to be approved by a different team member.
- Branch names should be in line with the new functionality and follow a structure:
  - Feature/branch-name
  - Fix/branch-name
- Branch name will be separated at each word with a hyphen(-):
  - Feature/this-is-a-branch
- Each commit should explain what new functionalities have been added or what pieces of code have been changed.

Using these strategies and naming conventions will allow us to keep the repository organized and able to roll back easily to an older branch if necessary.

# Merge requests

Merge requests (MR) provide a record of code changes and allows for review with the team members before merging it to the development branch. Before making a pull request one should have a look to see if making tests for the newly made feature is necessary. These tests will then be runned by the CI/CD pipeline. If these tests succeed, then the PR is ready to be requested.

When creating a MR there is a list to follow for a clear understanding for the reviewer what the MR is for and what changes have been made. this list is the following:

Insert this in the MR description:

*## Merge request checklist*

*Please check if your MR fulfills the following requirements (if needed):*

- *[x] Unit tests for the changes have been added*
- *[x] Cypress tests for the changes have been added*
- *[x] Project docs have been updated*

*## What is the new behavior?*

*Generated gitignore file includes jetbrains and a bunch of other stuff*

*## Screenshot (if applicable)*

*/*

*## Is further testing or are further changes required?*

- *[x] No*
- *[ ] Yes (Please provide further detail below.)*

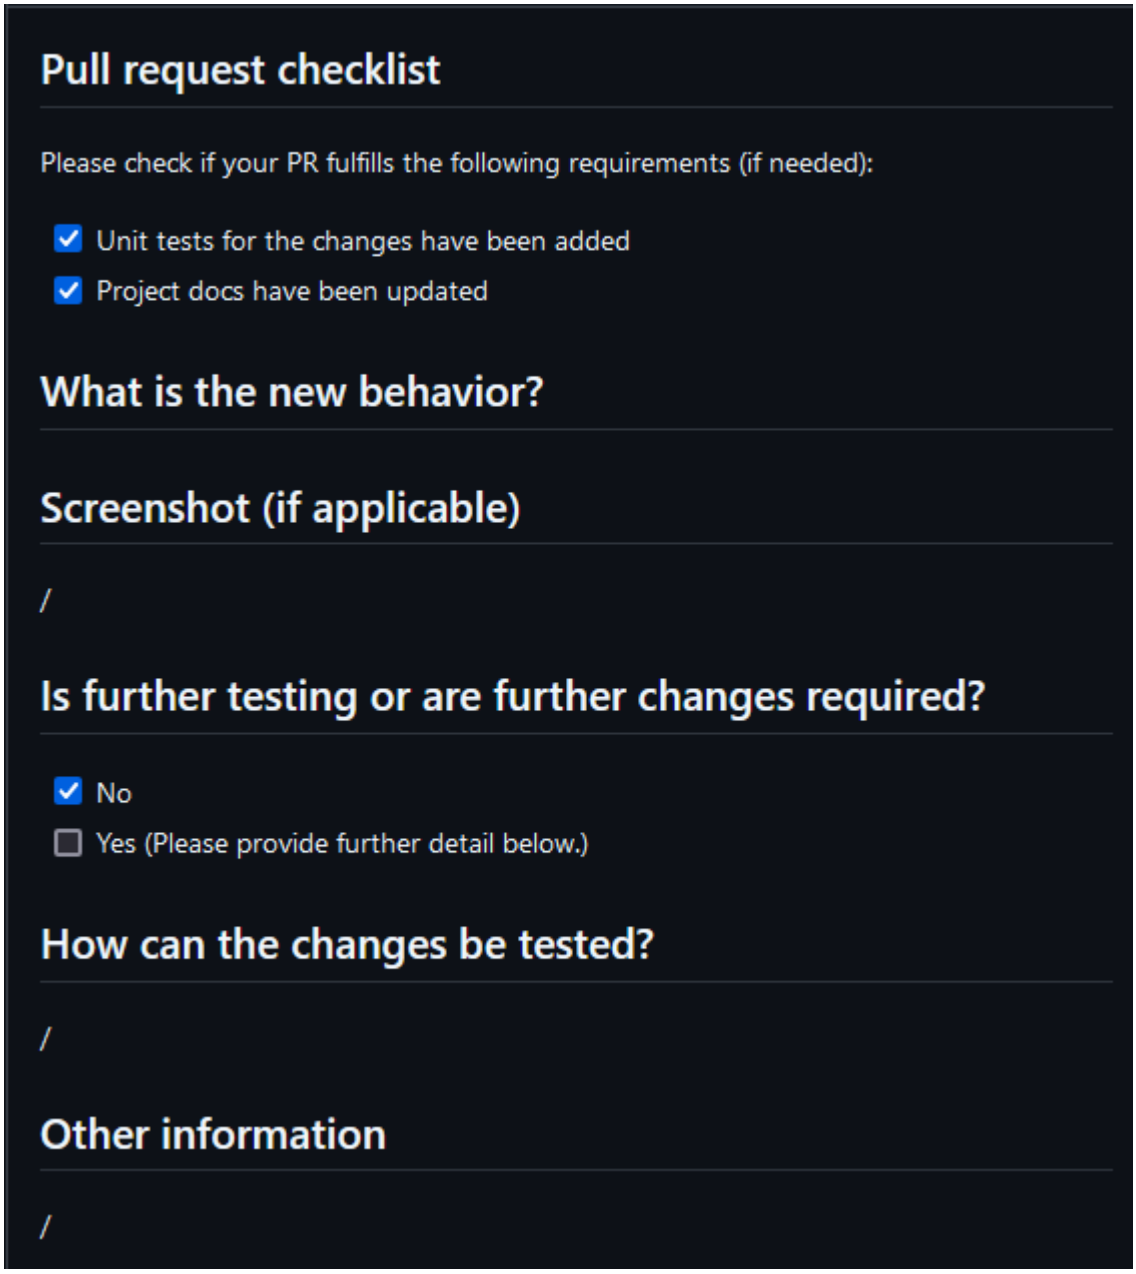

*## How can the changes be tested?*

*/*

*## Other information*

*/*

Which will result in this overview:

## Testing requirements

Testing prevents bugs from reaching the production and ensures code changes don't break existing features. All major features should have unit tests, integration tests or end-to-end tests based on the project's complexity and if making tests is applicable for the feature. These tests will be automatically performed by the automated GitLab pipelines which saves time running the tests yourself and catching issues early.
